Overvoltage controlled. ANYWHERE.

## PRACTICAL GUIDE

## Low-voltage power systems

Surge protection

Overvoltage

Since the 1960s, the purely technical term EMC (electromagnetic compatibility) has become a term comprising not only safety for appliances and components, but in particular, for their users. Apart from others, it refers to the resistance of devices and equipment to all forms of electromagnetic disturbance, including impulse overvoltage and high frequency disturbance. It is thus the suppliers who must increase the resistance of systems today. A correctly designed and installed system of surge protective devices and SALTEK ${ }^{\circledR}$ filters can satisfy even the most demanding requirements for the safety of equipment in terms of electromagnetic compatibility.

The current standard of technology offers good protection for electronic and electrical equipment against the effects of dangerous impulse overvoltage, i.e., surge arresters. Equipment can be protected not only against the effects of a destructive impulse that features great energy, but also against the effects of high frequency disturbances. Unprotected electrical wiring, computer and data networks always pose a huge risk for their users. Installing overvoltage protection devices therefore prevents possible damage. The price of surge arresters is only a tiny part of the cost expended on protected equipment and a negligible amount compared to the potential damage resulting from a failure or destruction of the technological equipment followed by financial losses.

SALTEK surge arresters comply to Czech and international standards.

Electronic components damaged by overvoltage

## Overvoltage types

Basically, overvoltage can be classed according to its duration.

## Transient overvoltage - short-term changes in voltage:

overvoltage that lasts a short time not exceeding several thousandths of a second, oscillating or non-oscillating, usually highly damped, in hundreds of microseconds (see Fig. 1a) such overvoltage can be successfully eliminated using an SPD (Surge Protective Device).

Temporary overvoltage - long-term changes in voltage:
overvoltage with industrial frequency of oscillation and a relatively long duration

- in milliseconds or less (see Fig. 1b)
- such overvoltage cannot be eliminated by means of an SPD.

Short-term changes in voltage, i.e. transient overvoltage can be classed in several groups according to the origin:

- differential mode of overvoltage: overvoltage between live conductors (L1-L2, L-N with LV supply, a-b with telecommunications...), such overvoltage occurs as a result of technological events - e.g. switching of non-linear loads (motors, refrigerators,...). These are particularly dangerous for electronic equipment, sensitive hardware-like control systems, computers and their software utilities, etc. (see Fig. 2)
- common-mode of overvoltage: overvoltage between the neutral conductor and earthing conductor (L-PE, N-PE in LV, a/b-PE in telecommunications...) that results from atmospheric events - a lightning strike. Such overvoltages are particularly dangerous for technological equipment, the frame of which is earthed (insulation breakdown). (see Fig. 3)

An SPD in the supply network will be selected according to the type of respective overvoltage.

Parameters of (current) impulse

The front time The time to half-value

$8 / 20 \mu \mathrm{~s}$ current impulse simulates surge from switching overvoltage or inductive coupling. This impulse is used for the classification of the SPD for class II test (SPD Type 2)

[^0]
## Protection of technological equipment against overvoltage

The principle of surge protective devices is based on equipotential bonding. This is conditioned by the effective equalising potential in the whole building. It is only possible if the whole building is thoroughly provided with equipotential bonding and it should be connected to the earthing electrode.

If a building features external lightning protection (LPS), both the down conductor as well as the protective conductor of the supply network should be connected to the earthing conductor. This is shown in the following chapter.

## Supply networks - SPD connection principles on how to connect SPDs

An SPD in power supply networks should be connected in two connection modes - mode x+0 (CT1) and mode x+1 (CT2).

The $\mathrm{x}+0$ (CT1) connection mode is designated $3+0(\mathrm{TN}-\mathrm{C})$ or $4+0$ (TN-S) for three-phase power supply and $1+0$ (TN-C) or $2+0$ (TN-S) for single-phase power supply. Such mode is beneficial in eliminating common mode of overvoltage.

The $x+1$ (CT2) connection mode is designated $3+1$ for threephase power supply and $1+1$ for single-phase power supply. It cannot be used in the TN-C supply network. It is advantageous to use it to eliminate the differential mode of overvoltage.

## TN-S system

An SPD Type 1 or SPD Type 1 and 2 should be located at the incoming supply side to the building (mostly in the main distribution board). These SPDs are mainly intended to restrict lightning electromagnetic impulses (lightning strikes) and therefore are connected in the $\mathrm{x}+0$ pattern, i.e. with all ( $\mathrm{L} 1, \mathrm{~L} 2, \mathrm{~L} 3$ and N ) conductors in live condition against the ground (PE).

An SPD Type 2 should be located in a subsidiary distribution board. In such supply networks, the SPD Type 2 can either be connected in the $\mathrm{x}+0$ mode (to eliminate longitudinal - lightning electromagnetic impulse) or in the $\mathrm{x}+1$ mode (to restrict overvoltage in the equipment).

In a TN-S supply network, connection of a Type 2 SPD must follow the type of overvoltage that will prevail in the supply network. Consequently, in industrial operations, where a great number of switching overvoltage occurs, it is more advantageous to connect the SPD Type 2 in the $x+1$ (CT2) mode, while in administrative and residential buildings it is better to connect the SPD Type 2 in the $x+0$ (CT1) mode.

An SPD Type 3 is always mounted close to the equipment to be protected.

## TN-C-S system

In a TN-C-S supply network, the SPD located before the point from which the PEN conductor separates to the N and PE conductors should always be connected in the $x+0$ mode. Behind the point of separation, the SPD Type 2 can be connected in both the $x+1$ mode or $x+0$, with the same principle to be followed as in a TN-S network, i.e., such type of connection should be chosen to better suit the respective situation.

Fig. 7

TN-S system

TN-C-S system

TN-C system
In a TN-C supply network, an SPD can only be connected in the $x+0$ (CT1) mode. Concerning the SPD Type 3, wired in the $\mathrm{x}+1$ (CT2) connection mode, the N conductor (blue) as well as the PE conductor (yellow-green) should always be connected to the PEN conductor.

TT system
For a TT supply network, in which only neutral conductors L1, L2, L3 are routed from the power source, all levels of SPD should always be connected in the $x+1$ (CT2) mode.

## Fig. 9

TN-C system

## Fig. 10

[^1]
## Principle of overcurrent protection using SPD

For overcurrent protection using SPD it is important to consider whether we should follow the protection priority principle, which is used in most installations, or the power supply priority principle.

In case of the protection priority principle the SPD is pre-protection only if the line protection value (fuse F1) is higher than of SPD in the catalogue (fuse F2), and the overcurrent protection of SPD has always the value specified in the manufacturer's catalogue (parameter - maximum overcurrent protection).

## An example of back-up fuse for SPD - FLP-B+C MAXI V - in different supply networks.

The catalogue value of maximum back-up fuse for FLP-B+C MAXI V is 250 A , and 125 A for the " V " connection.

## SPD dimensioning

Only the SPD Type 1 should be dimensioned. Dimensioning of the SPD Type 1 should be based on the calculation of the lightning protection level (LPL) for the lightning protection system (LPS). The table below shows minimum values of
the discharge lightning strike current to the pole considering the lightning protection (LPL) class of the building for the SPD Type 1.

| If the LPL value is not known, the worse scenario is anticipated |  |  | Low voltage networks |  |  |  |  |  |  |  |  |  |

## Selection of SPD at the incoming supply side to the building

For selection of the SPD Type 1 at the incoming supply to the building we use the table for SPD Type 1 dimensioning (see table 1). At the same time, it is necessary to consider the specific situation. Even if the calculation made according to the previous table shows that the Impulse current of SPD

Type 1 may be, for example, 12.5 kA in a $10 / 350 \mu \mathrm{~s}$ wave and the building is fed by external cabling, then the probability of a lightning strike into the outdoor line is high and the SPD Type 1 would be under-dimensioned.

Variants of SPD applications are shown in the following examples:

| Situation at the entrance of structure | Solution |
| :--- | :--- |
| A house with LPS, earthed antenna, or metallic roof, etc. | SPD Type $1 \boldsymbol{\iota}$ SPD Type $2 \boldsymbol{X}$ |
| A house with an overhead line | SPD Type $1 \downarrow$ SPD Type $2 \boldsymbol{X}$ |
| A house with earthed metallic parts or LPS nearby | SPD Type $1 \boldsymbol{\cup}$ SPD Type $2 \boldsymbol{X}$ |

A family house in a built-up area or a detached structure with or without LPS and overhead line

A family house in a built-up area without LPS and with an underground cable connection

Terrace houses with a common LPS and overhead line

Terrace houses with a common LPS and an underground cable connection

Block of flats; underground cable connection; upstream of power meter SPD T1 installation impossible.
Note: for situation where is not possible to install Type 1 SPD upstream of power meter

Administration building

## Commercial building

Commercial building of special importance

## Administrative and commercial premises

House with a single-phase power supply and LPS (LPL I)

## Reduction of overvoltage in LPZ zones

The principle of voltage reduction using zones lies in progressive reduction of the overvoltage level to a safe value that will not damage the specific equipment or technology.

To obtain a safe overvoltage value, the whole structure is divided into individual zones and the SPD is installed at the boundary between the zones.

## SPD mounting - principles

## Principle 1 - length of connecting conductors

If you want to protect equipment, there are several things to remember when installing an SPD, i.e., apart from its diverting ability, it is the maximum value of voltage protective level to be withheld by the equipment at its terminals considering the installation method. Protection level $U_{p}$ and the drop in voltage at the supply conductors $\Delta \mathrm{U}$ must not exceed the withstand voltage at the terminals of the equipment.

Fig. 11 clearly shows that the aggregate protection level is given by adding partial reductions in voltage, while such a sum must not exceed $80 \%$ of the withstand voltage $U_{w}$ at the terminals of the equipment.

$$
\mathrm{U}_{\mathrm{w}}>\mathrm{U}_{\mathrm{p}}+\Delta \mathrm{U}_{1}+\Delta \mathrm{U}_{2}
$$

where $\quad \bigcup_{w} \ldots$ withstand voltage
$U_{p} \ldots$ voltage protection level
$\Delta \mathrm{U}_{1}, \Delta \mathrm{U}_{2} \ldots$ reduction in voltage at the
supply conductor.

The impedance of supply conductors for high frequency currents is approximately $1 \mu \mathrm{H}$ per 1 m of conductor length.

The voltage drop in this conductor is given by the formula:

## $\Delta \mathrm{U}=\mathrm{L} \times \mathrm{di} / \mathrm{dt}$

So with a steepness of the pulse rise time of $1 \mathrm{kA} / \mu \mathrm{s}$, there is a reduction of $1,000 \mathrm{~V}$ per 1 m of length, which is added to the protection voltage level of the SPD itself. With the total length of supply conductors being $0.5 \mathrm{~m}, 500 \mathrm{~V}$ will be added to the protection voltage level U . Consequently, the length of the supply conductors must be as short as possible and should not exceed an aggregate length of 0.5 m , as shown in the following figures (Fig. 12 and Fig. 13), depicting the connection options.

## Fig. 13

The two pictures below illustrate how the stipulated conductor length of $\leq 0.5 \mathrm{~m}$ to connect the SPD can be met in practice.

Before the intervention: The SPD installation fails to meet the condition as regards the length of supply conductors for the SPD

After the intervention: By relocating the SPD the condition above will be satisfied. ren

Before the intervention: The SPD installation fails to meet the condition as regards the length of supply conductors

Principle 2 - Locating the SPD in the distribution board An SPD in the distribution board is located at the entry of the customer's structure, to eliminate as early as possible any surges entering the supply line, and to prevent their effects on appliances installed in the distribution board. It makes
sure the unprotected conductors (affected by overvoltage) are kept as short as possible and the overvoltage that could be induced in conductors protected by the SPD is minimized. Basic options are shown in Fig. 14.

Fig. 14

The next figure shows the practical implementation of the c) option displayed in Fig. 14.

Before the intervention: The SPD installation fails to meet the condition as regards the length of supply conductors for the SPD

After the intervention: By adding a terminal block and connecting a PEN conductor, these conditions will be satisfied

Before the intervention: The SPD installation fails to meet the condition as regards the length of supply conductors for the SPD and also the SPD connection for the TN-S system

After the intervention: By relocating the circuit breaker and the SPD, the conditions will be satisfied; and by adding one more SPD the $N$ conductor will also be protected.

## Principle 3 - loops

To minimize the overvoltage induced in a loop and to considerably reduce the effects of such overvoltages on other equipment connected in the distribution board, the surface of the
loop consisting of the $L, N$ and PE conductors must be kept as small as possible. The principle of minimizing the loop is shown in Fig. 14 and the following examples.

Before the intervention

After the intervention: By turning the SPD, the hardwiring in the distribution board will be better arranged and, at the same time, the condition from IEC 6164312/2008 (CLC/TS 61643-12/2009) concerning loops will be satisfied

Before the intervention
After the intervention: By relocating the SPD, the hardwiring in the distribution board will be better arranged, the condition concerning loops specified in IEC 61643-12/2008 (CLC/TS 61643-12/2009) will be satisfied and, at the same time, the condition stipulating the length of supply conductors for the SPD will be met as well

Principle 4 - conductor routing in the distribution board When routing the conductors in the distribution board it is always necessary to separate protected („clean") from unprotected („dirty") conductors. To minimise the bonding between the different types of conductors („clean" and "dirty"), it is essential to keep the distance between them as great as possible (over 30 cm ). If such a distance is impossible
to observe, a protective partition should be placed between them, see Fig. 15.
If you cannot avoid crossing of protected and unprotected conductors, the crossing should be made at a right angle to prevent induction of interference pulses in the protected conductors, as shown in Fig. 16.

## Coordination of SALTEK SPDs Rules

To achieve correct operation of individual SPD protection levels, specific distances should be observed between them. A general solution is shown in Fig. 17 and Fig. 19. Fig. 18 shows incorrect coordination between the individual SPDs.

Should it be impossible to observe the coordination distances between the specific protection levels, the distance can be extended using coordination RTO impedances. These coordination
impedances must be sized to the current flowing through the line. This can be established from the value of the circuit protection.

Since the usage of RTOs appears rather problematic for higher currents of long duration when the distances between the respective stages are not adhered to, it is the reason why coordinated SPDs of Type 1 with the corresponding SPD Type 2 are used.

See following figures for coordination of specific SPD Type 1 and SPD Type 2 by Saltek. If lightning arrester FLP-SG50 $\mathrm{V} / 1$ is used as an SPD Type 1 and SLP-275 V is used as an SPD Type 2, it will not be necessary to keep the distance between them in excess of 10 m since they are mutually coordinated and can be mounted next to each other (see Fig. 20). The same conditions apply to FLP-B+C MAXI V and FLP-25-T1-V.

Also for correct operation of the stages of the SPD Type 2 and SPD Type 3, minimum distances need to be adhered to. Again, a general design is shown in Fig. 17 and Fig. 19, and wrong coordination is shown in Fig. 18. Should no coordination distance can be maintained between SPD Type 2 and SPD Type 3, the distance can be again increased using the RTO coordination impedances, see Fig. 19. The coordination impedances need to be rated to the line current.

Fig. 20

## Relation between distance and selection of SPD

Since there are situations in practice where the equipment to be protected is connected directly from the main distribution board and the technology distribution board finds itself usually at a distance of tens of meters, it is advisable to install an SPD in the technology distribution board to cope with overvoltage as well as different earth potentials that might occur there, particularly if the earthing (equipotential bonding) is
not completely all the way through. Consequently, an SPD Type $1+2$, featuring a diverting ability of $I_{n}=30 \mathrm{kA}(8 / 20 \mu \mathrm{~s})$, should be installed in the position of the SPD Type 2, whose diverting ability is $I_{n}=20 \mathrm{kA}(8 / 20 \mu \mathrm{~s})$, to work $\mathrm{I}_{\mathrm{n}}$ this case as a strong SPD Type 2 (see Fig. 21-22 and Fig. 23-24). For more information see the table "SALTEK SPD applications in LV distribution systems", pages 31-32.

## Protective distance

To protect specific equipment, an SPD should be installed as close as possible to the protected equipment. If the distances between the SPDs or that between the SPD and the protected equipment are too long, voltages cause by oscilation phenomena may appear on the line which can destroy either the connected equipment or cause the breakdown of power line insulation. These oscilations can
even double the $U_{p}$ protection voltage level. The doubling effect occurs if the equipment is disconnected inside or its input impedance is high. If the distance between the SPD and the protected equipment is $L \leq 10 \mathrm{~m}$, the oscilations disturbing signals need not be taken into consideration. If the distance is great ( $L \gg 10 \mathrm{~m}$ ), remember to install an additional SPD (see Fig. 25-26 and Fig. 27-28).

In the practice, the protective distance of the SPD always decreases due to voltages induced by lightning currents or the switching of burdens connected in the loop circuit. This is why the distance between an SPD and the technology should never exceed 5 m .

This is of particular importance in protecting highly sensitive equipment, such as electronic security systems, electronic fire signalling systems, PLC and other processor-controlled technology that is also prone to induced switching overvolt-

age. Such overvoltage with a very short duration (in $\mu \mathrm{s}$ ) and a small pulse amplitude (hundreds of volts) would pass up to the equipment, which maybe will not destroy it but may cause the processor to freeze or damage or erase memory chips or impair the functionality of the equipment. Hence, an SPD Type 3 with a RFi filter, able to cope with this problem, should be installed in these cases. An example of the connection of an SPD Type 3 with a RFi filter is shown in Fig. 29 and Fig. 30.

## Socket circuits with SPD Type 3

Consideration should be taken regarding socket circuits, which are usually very long and are used in different situations. The protective distance of an SPD Type 3 in cabled socket circuits amounts to 5 m , at maximum, as shown in Fig. 32.

To ensure correct functioning of an SPD Type 3, both protection levels - SPD Type 1 and SPD Type 2 - should be mounted upstream.

Socket circuitry featuring all sockets either with integrated SPD Type 3 protection or available with SPD Type 3 protection for additional installation (see Fig. 31), is always used in heavily disturbed environments, or places with a larger number of electrical appliances installed. Laboratories are a typical example of such environment.

SPD Type 3 for additional installation

DA-275-A

DA-275-A

DA-275-A

DA-275-A
T3

In order to reduce the number of SPD Type 3 in the socket circuitry, protective distances between the SPDs Type 3 of less than 5 m are used as standard. In these cases it is not necessary to equip all sockets with SPD Type 3 protection. The basic principle to follow in this method of installing an SPD Type 3 is that the SPD must always be installed at the first socket in the socket circuit; the protective distance principle for SPD Type 3, as shown in Fig. 32, can be ap-
plied only after that. Fig. 33 shows an example of incorrect application of the protective distance. The principle of protective distance cannot be applied to situations where one side of the wall features a socket circuit with, for example, a down conductor bar or an unprotected ascending LV line situated on the other side of the wall. All sockets installed at this place should be provided with an SPD Type 3, as shown in Fig. 34 and Fig. 35.

If this principle is not observed, the problem located at the LV line bar will manifest itself in the socket circuit and will damage the equipment connected to the specific socket. Administrative buildings feature a great number of socket circuits with many sockets. To reduce the number of SPDs in such cases, not only the protective distance for the SPD

Type 3 is used, but also so-called installations in groups, as shown in the following examples. If distances between individual groups exceed 5 m , as shown in Fig. 36, the passage socket group must be provided with an SPD Type 3 at the first and last socket.

for example a down conductor

## Fig. 37

## Fig. 38

If the group is not a through-way group, an SPD Type 3 should always be installed at the first socket. Should the distance between individual socket groups be less than 5 m , then the property of the SPD protective distance can be used and the no an SPD Type 3 will be mounted on the through-way group - see Fig. 37. The principle of pro-
tective distance cannot be applied in situations where the distance between two groups is less than 5 m , and, for example, a down lead or an unprotected LV line is located on the other side of the wall. It is necessary in this case that the last socket of the through-way group be provided with an SPD Type 3. This option is shown in Fig. 38.

## SPDs connected to LV power supply systems up to 1000 V

## Lightning current arresters (SPD Type 1), spark-gap based

A high-performance spark gap specified for using in LV installations at the boundary of the LPZ 0 and LPZ 1 zones. Surge protection indirect as well as indirect lightning strikes in the hardest application in heavy, chemical and energy industry. Coordination with SPD Type 2 (SLP-275 V) without coupling impedances.
FLP-SG50 V(S)/1

- Pluggable module
- Visual fault signalling
- Module locking
- Optional remote fault signalling (S)
- $\mathrm{U}_{\mathrm{p}} \leq 2.5 \mathrm{kV}$

| Type | Connection | Suitable <br> networks | $\mathbf{U}_{\mathbf{c}}$ | $\mathbf{I}_{\text {imp }}$ <br> $(10 / 350$ <br> $\mu s)$ | $\mathbf{I}_{\mathrm{fi}}$ | Remote <br> signalling | Ordering number |

## SPDs connected to LV power supply systems up to 1000 V

## Lightning current arresters (SPD Type 1), serial combination MOV+GDT

Very high-performance lightning current arresters for LV installations at the boundary of the LPZ 0 and LPZ 1 zones or higher. For protection in direct as well as indirect lightning strikes. For using in a variety of installations, for family houses, office and industrial buildings, or in sub-distribution boards of large buildings. Coordination with SPD Type 2 (SLP-275 V) without coupling impedances. No leakage current. No follow current. Optional integrated back-up fuse.

## SPDs connected to LV power supply systems up to 1000 V

## Lightning current arresters and surge arresters (SPD Type 1 and 2) in electric vehicle charging stations

Combined lightning arrester and surge arresters designed to protect electric vehicle charging stations located in the LPZ 0 zone. Among other things, it fulfills the requirements of the energy company standard PNE 33 0000-5 for placing the SPD before the measurement (electricity meter). Zero leakage current. No subsequent current is generated.
FLP-EV12,5-VBH/.S+1

## Lightning current arresters and surge arresters (SPD Type 1 and 2), MOV based

For LV installations at the boundary of the LPZ 0 and LPZ 1 or higher. Protection against the effects of partial lightning strike currents, induced overvoltage in lightning strikes and against switching overvoltage. It is suitable for lightning protection levels III and IV of buildings, in subdistribution boards of large buildings or the protection of air conditioners or heating cables.

## SPDs connected to LV power supply systems up to 1000 V

## Surge arresters (SPD Type 2), MOV based

For LV installations, especially to sub-distribution boards. Protection of installation and devices against effects of induced surge during a lightning strike or switching surges.

## SPDs connected to LV power supply systems up to 1000 V

## Surge arresters (SPD Type 2), serial combination MOV+GDT

For protection of installations and devices against the effects of induced overvoltage in lightning strikes in areas with more frequent storms and against switching overvoltage. Suitable for supply by diesel-generator and networks with fluctuating voltages. For protection of measurement circuits as the first level of protection. It is also suitable for Instrumentation and control (I\&C) circuits at the boundary of the LPZ 0 and LPZ 1. No leakage current. No follow current.

## Surge protections (SPD Type 3) on the DIN rail, for parallel connection

A combination of varistor surge protection and an encapsulated spark gap connected in the $1+1$ ( $3+1$ ) mode. For LV installations at the boundary of the LPZ 2 and LPZ 3 zones. For protection installations and devices against the effects of induced overvoltage in lightning strikes and against switching overvoltage. Location as close as possible to the protected device.
DA-275 V/... (S)

## SPDs connected to LV power supply systems up to 1000 V

## Coordination impedance RTO-...

Coupling impedance to secure proper coordination of a SPD if the minimum distance between a SPD Type 1 and SPD Type 2, which exceeds 10 m , is not maintained, or a Type 2 and Type 3 SPD, which exceeds 5 m .

## Surge protection (SPD Type 3 and Type 2 and 3) for LED lights

SPDs mainly for drivers of LED lights. Instalation close to protected equipment into LV power circuits. Also for equipments in external part of structure with low or high exposure level (according IEEE C62.41.2). Fault signalling by supply interruption.

SP-T2+T3-320/Y-...-LED

- For equipment in external part of building with low exposure level
- $\mathrm{U}_{\mathrm{p}} \leq 1.5 \mathrm{kV}$

- For equipment in external part of building with high exposure level
- $\mathrm{U}_{\mathrm{p}} \leq 1.5 \mathrm{kV}$
